#### **Neural Networks**

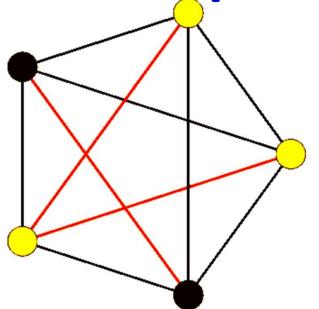

## Hopfield Nets and Boltzmann Machines Fall 2022

## Recap: Hopfield network

- Symmetric loopy network
- Each neuron is a perceptron with +1/-1 output

## Recap: Hopfield network

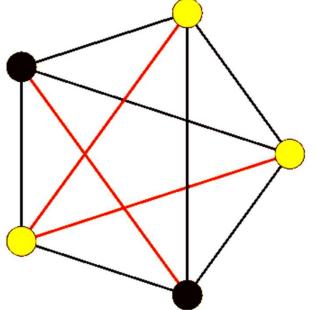

$$y_i = \Theta\left(\sum_{j \neq i} w_{ji} y_j + b_i\right)$$

$$\Theta(z) = \begin{cases} +1 & \text{if } z > 0 \\ -1 & \text{if } z \le 0 \end{cases}$$

- At each time each neuron receives a "field"  $\sum_{j \neq i} w_{ji} y_j + b_i$
- If the sign of the field matches its own sign, it does not respond
- If the sign of the field opposes its own sign, it "flips" to match the sign of the field

### Recap: Energy of a Hopfield Network

$$y_i = \Theta\left(\sum_{j \neq i} w_{ji} y_j\right)$$

$$\Theta(z) = \begin{cases} +1 & \text{if } z > 0 \\ -1 & \text{if } z \le 0 \end{cases}$$

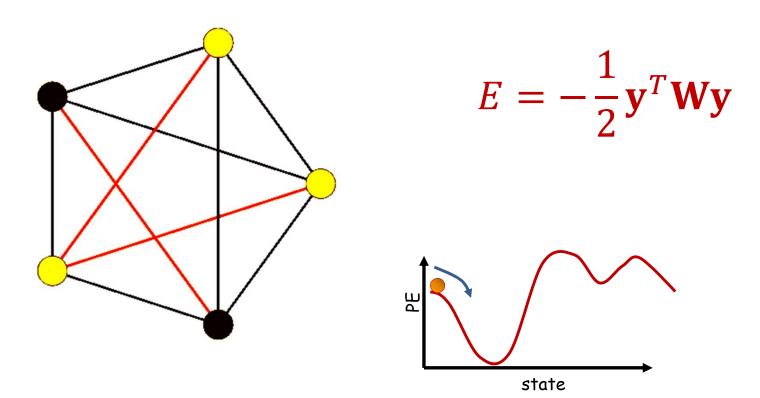

Not assuming node bias

$$E = -\sum_{i,j < i} w_{ij} y_i y_j$$

- The system will evolve until the energy hits a local minimum
- In vector form, including a bias term (not typically used in Hopfield nets)

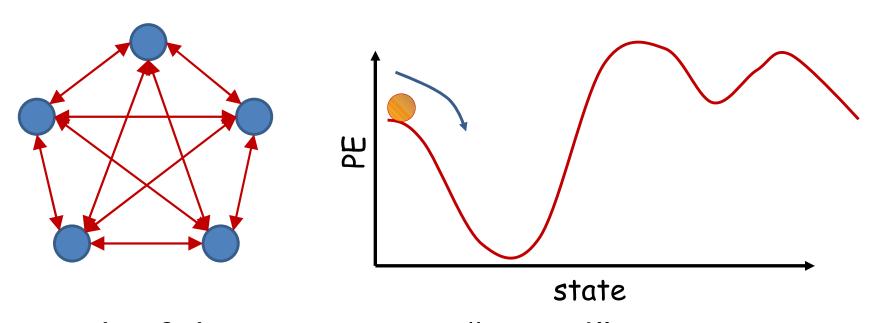

$$E = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} - \mathbf{b}^T\mathbf{y}$$

## **Recap: Evolution**

 The network will evolve until it arrives at a local minimum in the energy contour

#### Recap: Content-addressable memory

- Each of the minima is a "stored" pattern
  - If the network is initialized close to a stored pattern, it will inevitably evolve to the pattern
- This is a content addressable memory
  - Recall memory content from partial or corrupt values
- Also called associative memory

# **Examples: Content addressable**memory

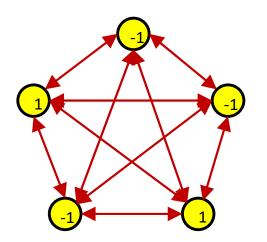

Hopfield network reconstructing degraded images from noisy (top) or partial (bottom) cues.

http://staff.itee.uq.edu.au/janetw/cmc/chapters/Hopfield/

## "Training" the network

- How do we make the network store a specific pattern or set of patterns?
  - Hebbian learning
  - Geometric approach
  - Optimization
- Secondary question
  - How many patterns can we store?

## Recap: Hebbian Learning to Store a Specific Pattern

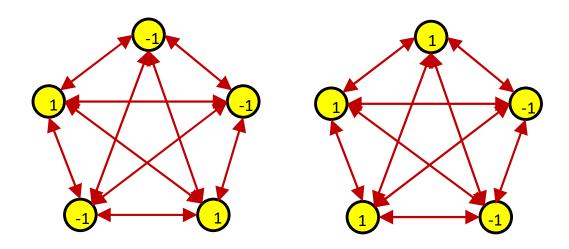

#### **HEBBIAN LEARNING:**

$$w_{ji} = y_j y_i$$

$$\mathbf{W} = \mathbf{y}_p \mathbf{y}_p^T - \mathbf{I}$$

 For a single stored pattern, Hebbian learning results in a network for which the target pattern is a global minimum

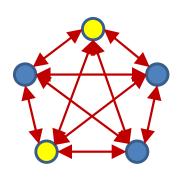

## Storing multiple patterns

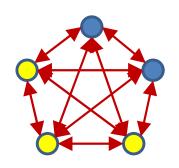

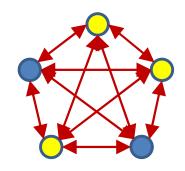

$$w_{ji} = \sum_{p \in \{y_p\}} y_i^p y_j^p$$

- $\{y_p\}$  is the set of patterns to store
- Superscript p represents the specific pattern

### How many patterns can we store?

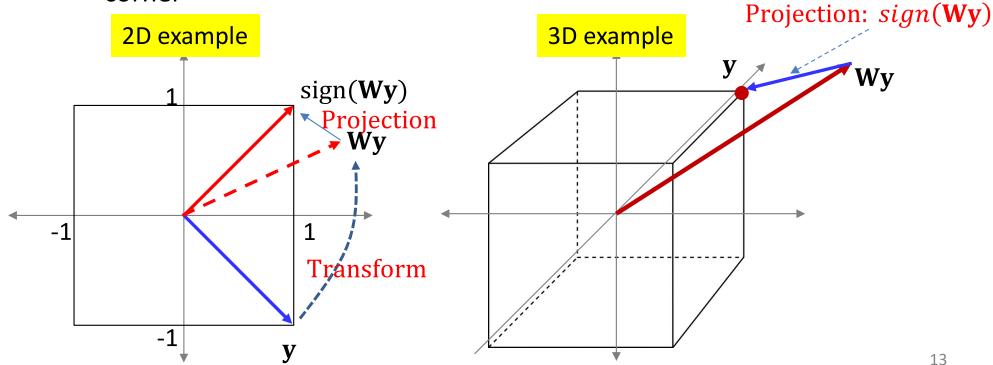

- Hopfield: For a network of N neurons can store up to 0.14N random patterns
- In reality, seems possible to store K > 0.14N patterns
  - i.e. obtain a weight matrix W such that K > 0.14N patterns are stationary

## "Training" the network

- How do we make the network store a specific pattern or set of patterns?
  - Hebbian learning
  - Geometric approach
  - Optimization
- Secondary question
  - How many patterns can we store?

#### **Evolution of the network**

- Note: for real vectors sign(y) is a projection
  - Projects y onto the nearest corner of the hypercube
  - It "quantizes" the space into orthants
- Response to field:  $\mathbf{y} \leftarrow sign(\mathbf{W}\mathbf{y})$ 
  - Each step rotates the vector y and then projects it onto the nearest corner

## **Storing patterns**

- A pattern  $\mathbf{y}_P$  is stored if:
  - $-sign(\mathbf{W}\mathbf{y}_p) = \mathbf{y}_p$  for all target patterns
- Training: Design W such that this holds
- Simple solution:  $\mathbf{y}_p$  is an Eigenvector of  $\mathbf{W}$ 
  - And the corresponding Eigenvalue is positive  $\mathbf{W}\mathbf{y}_p = \lambda\mathbf{y}_p$
  - More generally orthant( $\mathbf{W}\mathbf{y}_p$ ) = orthant( $\mathbf{y}_p$ )
- How many such  $\mathbf{y}_p$  can we have?

## Storing more than one pattern

- Requirement: Given  $y_1, y_2, ..., y_P$ 
  - Design W such that
    - $sign(\mathbf{W}\mathbf{y}_p) = \mathbf{y}_p$  for all target patterns
    - There are no other binary vectors for which this holds

 What is the largest number of patterns that can be stored?

## Storing K orthogonal patterns

- Simple solution: Design  $\mathbf{W}$  such that  $\mathbf{y}_1$ ,  $\mathbf{y}_2$ , ...,  $\mathbf{y}_K$  are the Eigen vectors of  $\mathbf{W}$ 
  - $\text{Let } \mathbf{Y} = [\mathbf{y}_1 \ \mathbf{y}_2 \ ... \ \mathbf{y}_K]$

$$\mathbf{W} = \mathbf{Y} \wedge \mathbf{Y}^T$$

- $-\lambda_1, \dots, \lambda_K$  are positive
- For  $\lambda_1=\lambda_2=\lambda_K=1$  this is exactly the Hebbian rule
- The patterns are provably stationary

## Storing N orthogonal patterns

- The N orthogonal patterns  $\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_N$  span the space
- Any pattern y can be written as

$$\mathbf{y} = a_1 \mathbf{y}_1 + a_2 \mathbf{y}_2 + \dots + a_N \mathbf{y}_N$$

$$\mathbf{W} \mathbf{y} = a_1 \mathbf{W} \mathbf{y}_1 + a_2 \mathbf{W} \mathbf{y}_2 + \dots + a_N \mathbf{W} \mathbf{y}_N$$

$$= a_1 \mathbf{y}_1 + a_2 \mathbf{y}_2 + \dots + a_N \mathbf{y}_N = \mathbf{y}$$

- All patterns are stationary
  - Remembers everything
  - Completely useless network

## Hebbian rule and general (nonorthogonal) vectors

$$w_{ji} = \sum_{p \in \{p\}} y_i^p y_j^p$$

- What happens when the patterns are not orthogonal
- What happens when the patterns are presented more than once
  - Different patterns presented different numbers of times
  - Equivalent to having unequal Eigen values...
- Can we predict the evolution of any vector y
  - Hint: For real valued vectors, use Lanczos iterations
    - Can write  $\mathbf{Y}_P = \mathbf{U}_P \Lambda \mathbf{V}_p^T$ ,  $\rightarrow \mathbf{W} = \mathbf{U}_P \Lambda^2 \mathbf{U}_p^T$
  - Tougher for binary vectors (NP)

#### The bottom line

- With a network of N units (i.e. N-bit patterns)
- The maximum number of stationary patterns is actually exponential in N
  - McElice and Posner, 84'
  - E.g. when we had the Hebbian net with N orthogonal base patterns, all patterns are stationary
- For a *specific* set of K patterns, we can *always* build a network for which all K patterns are stable provided  $K \leq N$ 
  - Mostafa and St. Jacques 85'
    - For large N, the upper bound on K is actually N/4logN
      - McElice et. Al. 87'
  - But this may come with many "parasitic" memories

#### The bottom line

- With an network of N units (i.e. N-bit patterns)
- The maximum number of stable patterns is actually exponential in N
  - McElice and Posner, 84'
  - E.g. when we had the F
     patterns, all patterns are stable

How do we find this network?

- For a *specific* set of K patterns, we can *always* build a network for which all K patterns are stable provided  $K \leq N$ 
  - Mostafa and St. Jacques 85'
    - For large N, the upper bound on K is actually N/4logN
      - McElice et. Al. 87'
  - But this may come with many "parasitic" memories

#### The bottom line

- With an network of N units (i.e. N-bit patterns)
- The maximum number of stable patterns is actually exponential in N
  - McElice and Posner, 84'
  - E.g. when we had the F
     patterns, all patterns are stable

How do we find this network?

se

Can we do something

- For a *specific* set of K patterns, we can *always* build a network for which all K patterns are stable provided  $K \leq N$ 
  - Mostafa and St. Jacques 85'

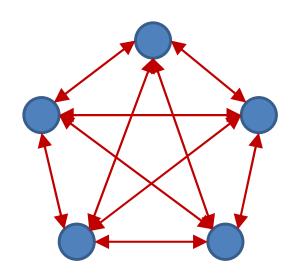

• For large N, the upper bound on K is actually 19

- McElice et. Al. 87'
- But this may come with many "parasitic" memories

#### A different tack

- How do we make the network store a specific pattern or set of patterns?
  - Hebbian learning
  - Geometric approach
  - Optimization
- Secondary question
  - How many patterns can we store?

## Consider the energy function

$$E = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} - \mathbf{b}^T\mathbf{y}$$

- This must be maximally low for target patterns
- Must be maximally high for all other patterns
  - So that they are unstable and evolve into one of the target patterns

## Alternate Approach to Estimating the Network

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} - \mathbf{b}^T\mathbf{y}$$

- Estimate W (and b) such that
  - E is minimized for  $y_1, y_2, ..., y_P$
  - -E is maximized for all other y
- Caveat: Unrealistic to expect to store more than N patterns, but can we make those N patterns memorable

## **Optimizing W (and b)**

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y}$$
  $\widehat{\mathbf{W}} = \underset{\mathbf{w}}{\operatorname{argmin}} \sum_{\mathbf{v} \in \mathbf{Y}_P} E(\mathbf{y})$ 

The bias can be captured by another fixed-value component

- Minimize total energy of target patterns
  - Problem with this?

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T \mathbf{W} \mathbf{y}$$

$$\widehat{\mathbf{W}} = \underset{\mathbf{W}}{\operatorname{argmin}} \sum_{\mathbf{y} \in \mathbf{Y}_P} E(\mathbf{y}) - \sum_{\mathbf{y} \notin \mathbf{Y}_P} E(\mathbf{y})$$

- Minimize total energy of target patterns
- Maximize the total energy of all non-target patterns

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} \qquad \widehat{\mathbf{W}} = \underset{\mathbf{w}}{\operatorname{argmin}} \sum_{\mathbf{y} \in \mathbf{Y}_P} E(\mathbf{y}) - \sum_{\mathbf{y} \notin \mathbf{Y}_P} E(\mathbf{y})$$

Simple gradient descent:

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T \right)$$

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T \right)$$

- Can "emphasize" the importance of a pattern by repeating
  - More repetitions → greater emphasis

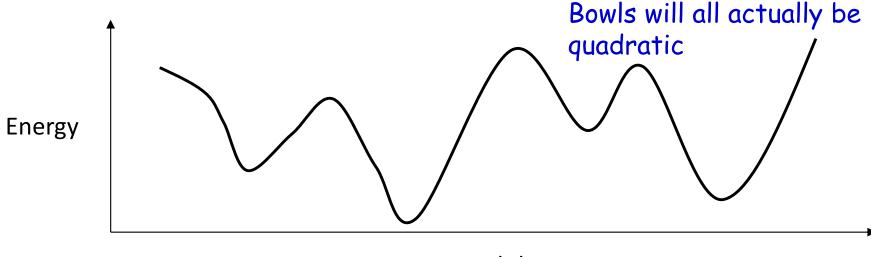

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T \right)$$

- Can "emphasize" the importance of a pattern by repeating
  - More repetitions -> greater emphasis
- How many of these?
  - Do we need to include all of them?
  - Are all equally important?

## The training again...

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T \right)$$

 Note the energy contour of a Hopfield network for any weight W

## The training again

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T \right)$$

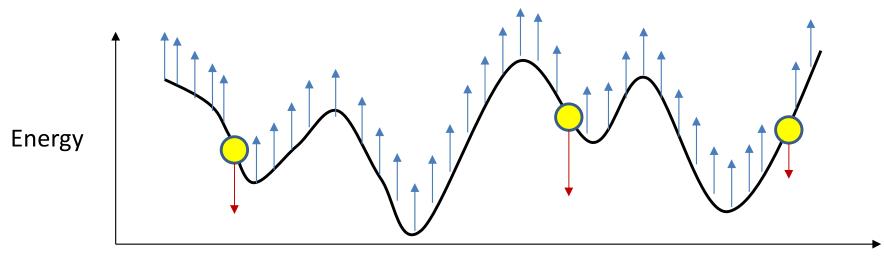

- The first term tries to minimize the energy at target patterns
  - Make them local minima
  - Emphasize more "important" memories by repeating them more frequently

## The negative class

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T \right)$$

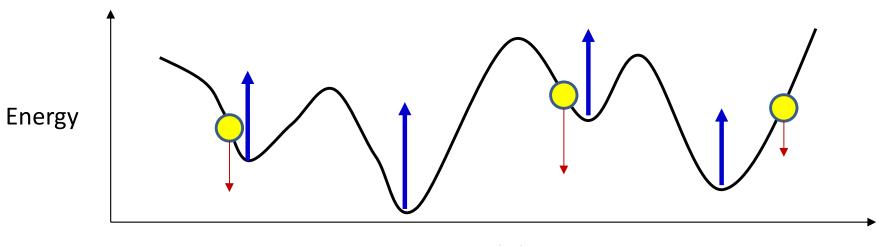

- The second term tries to "raise" all non-target patterns
  - Do we need to raise everything?

## Option 1: Focus on the valleys

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

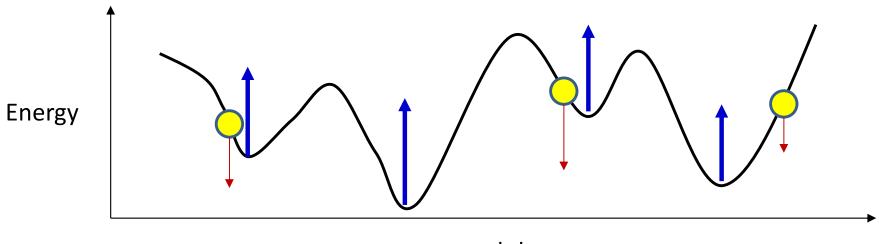

- Focus on raising the valleys
  - If you raise every valley, eventually they'll all move up above the target patterns, and many will even vanish

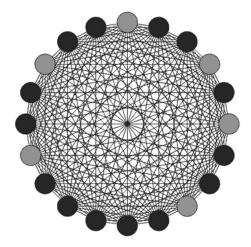

## Identifying the valleys...

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

 Problem: How do you identify the valleys for the current W?

## Identifying the valleys...

- Initialize the network randomly and let it evolve
  - It will settle in a valley

## Training the Hopfield network

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

- Initialize W
- Compute the total outer product of all target patterns
  - More important patterns presented more frequently
- Randomly initialize the network several times and let it evolve
  - And settle at a valley
- Compute the total outer product of valley patterns
- Update weights

# Training the Hopfield network: SGD version

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

- Initialize W
- Do until convergence, satisfaction, or death from boredom:
  - Sample a target pattern  $\mathbf{y}_p$ 
    - Sampling frequency of pattern must reflect importance of pattern
  - Randomly initialize the network and let it evolve
    - And settle at a valley  $\mathbf{y}_v$
  - Update weights

• 
$$\mathbf{W} = \mathbf{W} + \eta (\mathbf{y}_p \mathbf{y}_p^T - \mathbf{y}_v \mathbf{y}_v^T)$$

# Training the Hopfield network

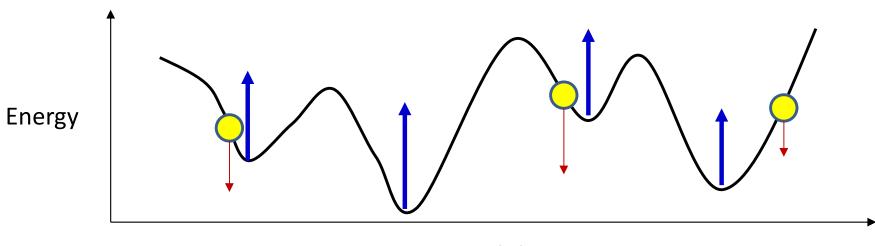

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

- Initialize W
- Do until convergence, satisfaction, or death from boredom:
  - Sample a target pattern  $\mathbf{y}_p$ 
    - Sampling frequency of pattern must reflect importance of pattern
  - Randomly initialize the network and let it evolve
    - And settle at a valley  $\mathbf{y}_v$
  - Update weights

• 
$$\mathbf{W} = \mathbf{W} + \eta (\mathbf{y}_p \mathbf{y}_p^T - \mathbf{y}_v \mathbf{y}_v^T)$$

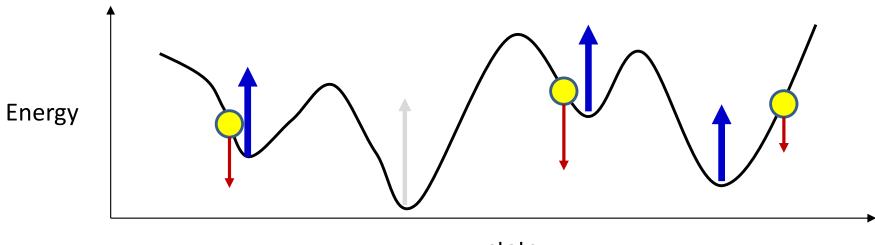

# Which valleys?

- Should we randomly sample valleys?
  - Are all valleys equally important?

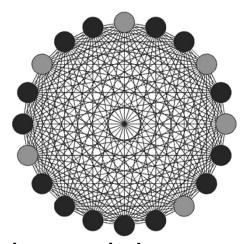

# Which valleys?

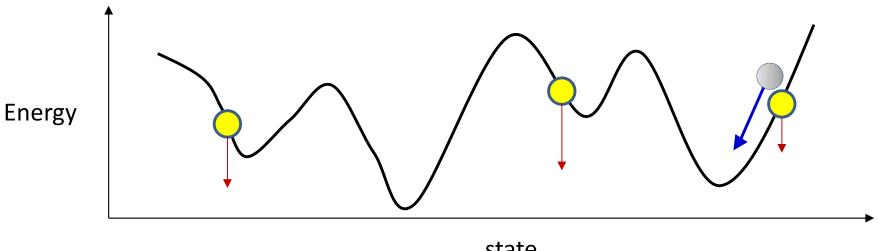

- Should we randomly sample valleys?
  - Are all valleys equally important?
- Major requirement: memories must be stable
  - They must be broad valleys
- Spurious valleys in the neighborhood of memories are more important to eliminate

# Identifying the valleys...

- Initialize the network at valid memories and let it evolve
  - It will settle in a valley. If this is not the target pattern, raise it

# Training the Hopfield network

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

- Initialize W
- Compute the total outer product of all target patterns
  - More important patterns presented more frequently
- Initialize the network with each target pattern and let it evolve
  - And settle at a valley
- Compute the total outer product of valley patterns
- Update weights

# Training the Hopfield network: SGD version

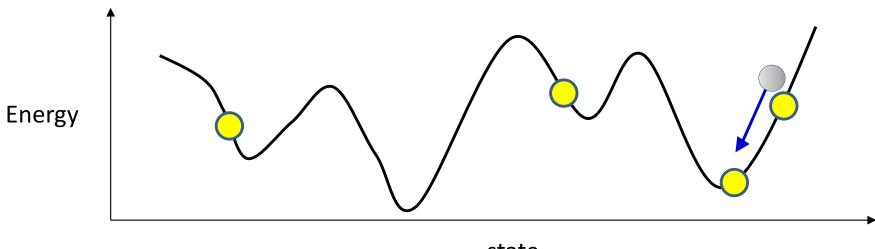

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

- Initialize W
- Do until convergence, satisfaction, or death from boredom:
  - Sample a target pattern  $\mathbf{y}_p$ 
    - Sampling frequency of pattern must reflect importance of pattern
  - Initialize the network at  $\mathbf{y}_p$  and let it evolve
    - And settle at a valley  $\mathbf{y}_v$
  - Update weights

• 
$$\mathbf{W} = \mathbf{W} + \eta (\mathbf{y}_p \mathbf{y}_p^T - \mathbf{y}_v \mathbf{y}_v^T)$$

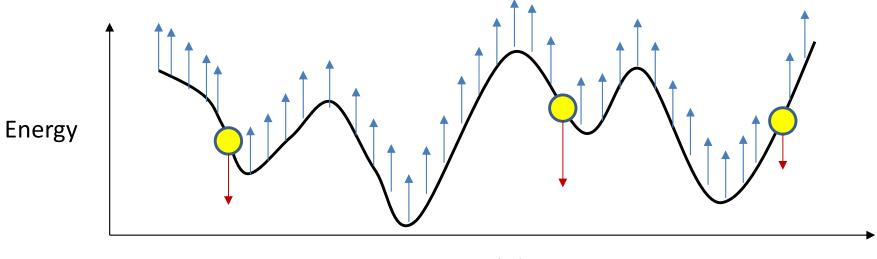

## A possible problem

- What if there's another target pattern downvalley
  - Raising it will destroy a better-represented or stored pattern!

### A related issue

 Really no need to raise the entire surface, or even every valley

45

### A related issue

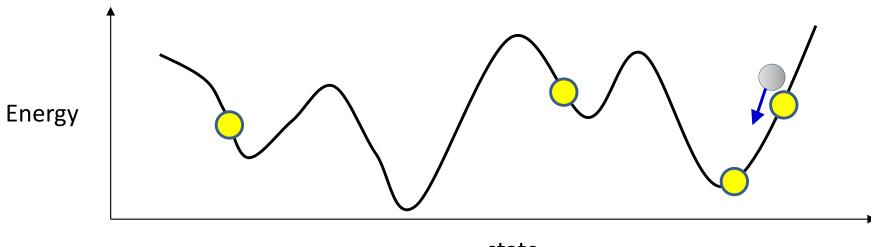

- Really no need to raise the entire surface, or even every valley
- Raise the neighborhood of each target memory
  - Sufficient to make the memory a valley
  - The broader the neighborhood considered, the broader the valley

46

# Raising the neighborhood

- Starting from a target pattern, let the network evolve only a few steps
  - Try to raise the resultant location
- Will raise the neighborhood of targets
- Will avoid problem of down-valley targets

# Training the Hopfield network: SGD version

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P \& \mathbf{y} = valley} \mathbf{y} \mathbf{y}^T \right)$$

- Initialize W
- Do until convergence, satisfaction, or death from boredom:
  - Sample a target pattern  $\mathbf{y}_p$ 
    - Sampling frequency of pattern must reflect importance of pattern
  - Initialize the network at  $\mathbf{y}_p$  and let it evolve  $\boldsymbol{a}$  few steps (2-4)
    - And arrive at a down-valley position  $\mathbf{y}_d$
  - Update weights

• 
$$\mathbf{W} = \mathbf{W} + \eta (\mathbf{y}_p \mathbf{y}_p^T - \mathbf{y}_d \mathbf{y}_d^T)$$

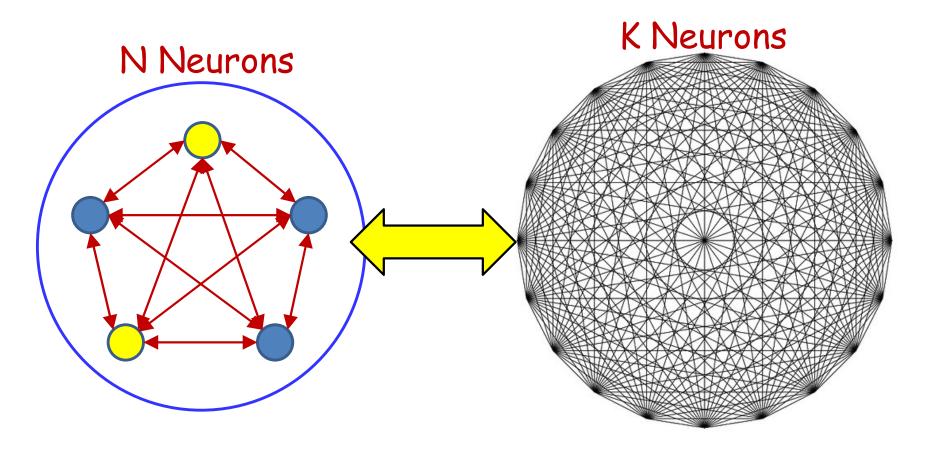

# Story so far

- Hopfield nets with N neurons can store up to 0.14N patterns through Hebbian learning
  - Issue: Hebbian learning assumes all patterns to be stored are equally important
- In theory the number of intentionally stored patterns (stationary and stable) can be as large as N
  - But comes with many parasitic memories
- Networks that store O(N) memories can be trained through optimization
  - By minimizing the energy of the target patterns, while increasing the energy of the neighboring patterns

### Storing more than N patterns

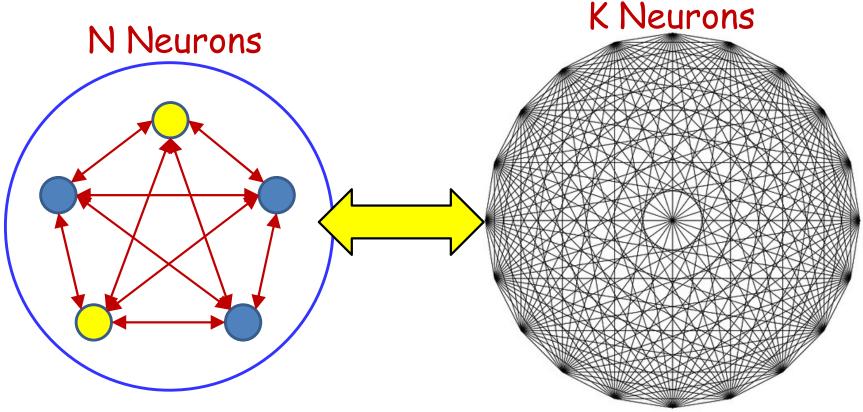

- The memory capacity of an N-bit network is at most N
  - Stable patterns (not necessarily even stationary)
    - Abu Mustafa and St. Jacques, 1985
    - Although "information capacity" is  $\mathcal{O}(N^3)$
- How do we increase the capacity of the network
  - How to store more than N patterns

## **Expanding the network**

 Add a large number of neurons whose actual values you don't care about!

## **Expanded Network**

- New capacity:  $\sim (N + K)$  patterns
  - Although we only care about the pattern of the first N neurons
  - We're interested in N-bit patterns

# **Terminology**

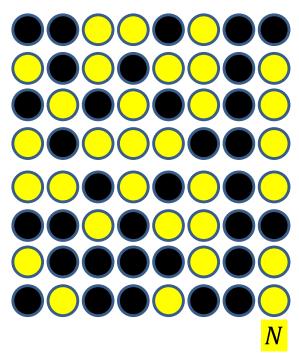

#### Terminology:

- The neurons that store the actual patterns of interest: Visible neurons
- The neurons that only serve to increase the capacity but whose actual values are not important: Hidden neurons
- These can be set to anything in order to store a visible pattern

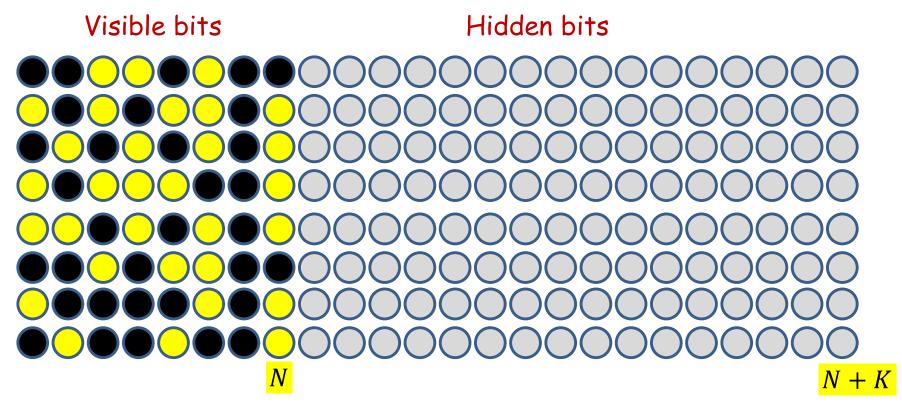

# Increasing the capacity: bits view

Visible bits

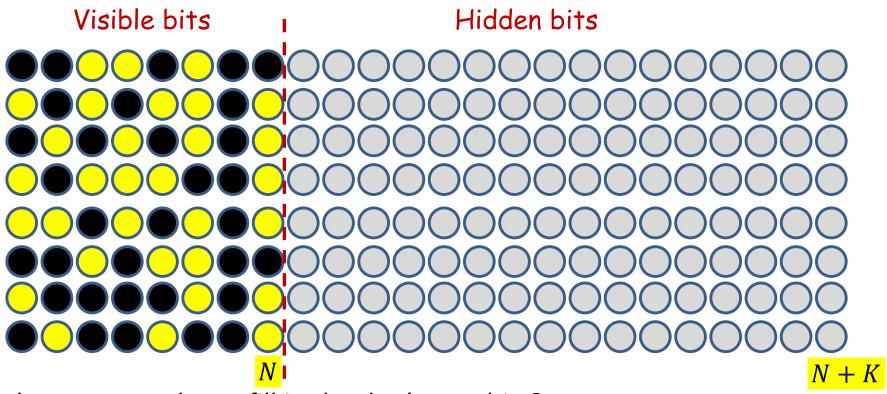

• The maximum number of patterns the net can store is bounded by the width *N* of the patterns..

### Increasing the capacity: bits view

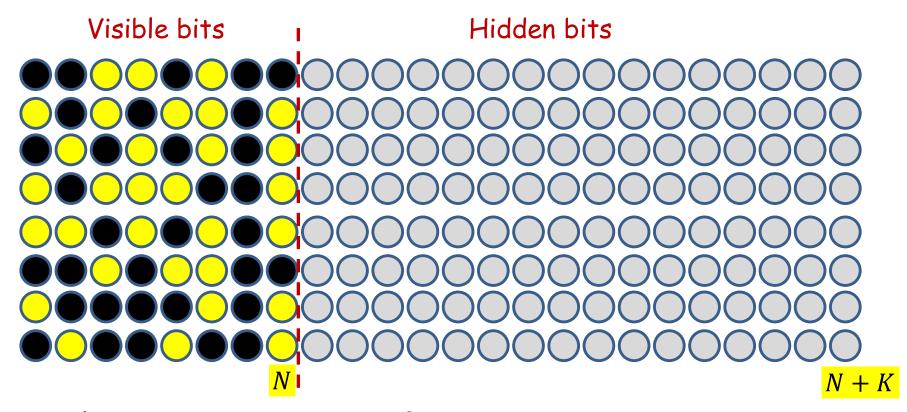

- The maximum number of patterns the net can store is bounded by the width *N* of the patterns..
- So lets pad the patterns with K "don't care" bits
  - The new width of the patterns is N+K
  - Now we can store N+K patterns!

### **Issues: Storage**

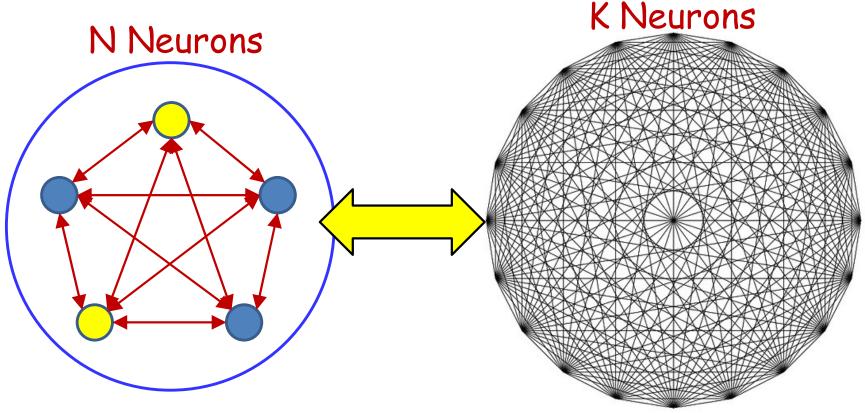

- What patterns do we fill in the don't care bits?
  - Simple option: Randomly
    - Flip a coin for each bit
  - We could even compose multiple extended patterns for a base pattern to increase the probability that it will be recalled properly
    - Recalling any of the extended patterns from a base pattern will recall the base pattern
- How do we store the patterns?
  - Standard optimization method should work

### **Issues: Recall**

- How do we retrieve a memory?
- Can do so using usual "evolution" mechanism
- But this is not taking advantage of a key feature of the extended patterns:
  - Making errors in the don't care bits doesn't matter

### **Robustness of recall**

- The value taken by the K hidden neurons during recall doesn't really matter
  - Even if it doesn't match what we actually tried to store
- Can we take advantage of this somehow?

### Taking advantage of don't care bits

 Simple random setting of don't care bits, and using the usual training and recall strategies for Hopfield nets should work

- However, it doesn't sufficiently exploit the redundancy of the don't care bits
- To exploit it properly, it helps to view the Hopfield net differently: as a probabilistic machine

# A probabilistic interpretation of Hopfield Nets

- For binary y the energy of a pattern is the analog of the negative log likelihood of a Boltzmann distribution
  - Minimizing energy maximizes log likelihood

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} \qquad P(\mathbf{y}) = Cexp(-E(\mathbf{y}))$$

### **The Boltzmann Distribution**

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^{T}\mathbf{W}\mathbf{y} - \mathbf{b}^{T}\mathbf{y} \qquad P(\mathbf{y}) = Cexp\left(\frac{-E(\mathbf{y})}{kT}\right)$$
$$C = \frac{1}{\sum_{\mathbf{y}} exp\left(\frac{-E(\mathbf{y})}{kT}\right)}$$

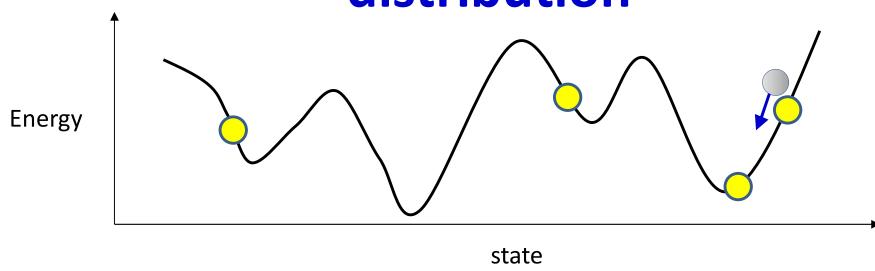

- k is the Boltzmann constant
- T is the temperature of the system
- The energy terms are the negative loglikelihood of a Boltzmann distribution at T=1 to within an additive constant
  - Derivation of this probability is in fact quite trivial..

# **Continuing the Boltzmann analogy**

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^{T}\mathbf{W}\mathbf{y} - \mathbf{b}^{T}\mathbf{y} \qquad P(\mathbf{y}) = Cexp\left(\frac{-E(\mathbf{y})}{kT}\right)$$
$$C = \frac{1}{\sum_{\mathbf{y}} exp\left(\frac{-E(\mathbf{y})}{kT}\right)}$$

- The system probabilistically selects states with lower energy
  - With infinitesimally slow cooling, at T=0, it arrives at the global minimal state

# Spin glasses and the Boltzmann distribution

- Selecting a next state is analogous to drawing a sample from the Boltzmann distribution at T=1, in a universe where k=1
  - Energy landscape of a spin-glass model: Exploration and characterization, Zhou and Wang, Phys. Review E 79, 2009

# **Hopfield nets: Optimizing W**

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} \qquad \widehat{\mathbf{W}} = \underset{\mathbf{w}}{\operatorname{argmin}} \sum_{\mathbf{y} \in \mathbf{Y}_P} E(\mathbf{y}) - \sum_{\mathbf{y} \notin \mathbf{Y}_P} E(\mathbf{y})$$

Simple gradient descent:

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \alpha_{\mathbf{y}} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \beta(E(\mathbf{y})) \mathbf{y} \mathbf{y}^T \right)$$

More importance to more frequently presented memories

More importance to more attractive spurious memories

# **Hopfield nets: Optimizing W**

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} \qquad \widehat{\mathbf{W}} = \underset{\mathbf{w}}{\operatorname{argmin}} \sum_{\mathbf{y} \in \mathbf{Y}_P} E(\mathbf{y}) - \sum_{\mathbf{y} \notin \mathbf{Y}_P} E(\mathbf{y})$$

Simple gradient descent:

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \alpha_{\mathbf{y}} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \beta(E(\mathbf{y})) \mathbf{y} \mathbf{y}^T \right)$$

More importance to more frequently presented memories

More importance to more attractive spurious memories

THIS LOOKS LIKE AN EXPECTATION!

# **Hopfield nets: Optimizing W**

$$E(\mathbf{y}) = -\frac{1}{2}\mathbf{y}^T\mathbf{W}\mathbf{y} \qquad \widehat{\mathbf{W}} = \underset{\mathbf{w}}{\operatorname{argmin}} \sum_{\mathbf{y} \in \mathbf{Y}_P} E(\mathbf{y}) - \sum_{\mathbf{y} \notin \mathbf{Y}_P} E(\mathbf{y})$$

Update rule

$$\mathbf{W} = \mathbf{W} + \eta \left( \sum_{\mathbf{y} \in \mathbf{Y}_P} \alpha_{\mathbf{y}} \mathbf{y} \mathbf{y}^T - \sum_{\mathbf{y} \notin \mathbf{Y}_P} \beta(E(\mathbf{y})) \mathbf{y} \mathbf{y}^T \right)$$
$$\mathbf{W} = \mathbf{W} + \eta \left( E_{\mathbf{y} \sim \mathbf{Y}_P} \mathbf{y} \mathbf{y}^T - E_{\mathbf{y} \sim \mathbf{Y}} \mathbf{y} \mathbf{y}^T \right)$$

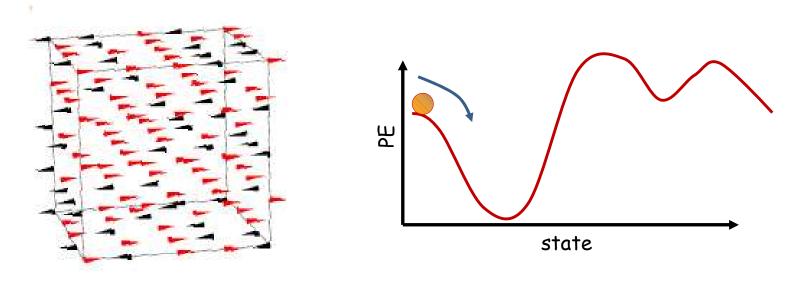

Natural distribution for variables: The Boltzmann Distribution

# From Analogy to Model

 The behavior of the Hopfield net is analogous to annealed dynamics of a spin glass characterized by a Boltzmann distribution

 So let's explicitly model the Hopfield net as a distribution..

### **Revisiting Thermodynamic Phenomena**

- Is the system actually in a specific state at any time?
- No the state is actually continuously changing
  - Based on the temperature of the system
    - At higher temperatures, state changes more rapidly
- What is actually being characterized is the *probability* of the state
  - And the expected value of the state

- A thermodynamic system at temperature T can exist in one of many states
  - Potentially infinite states
  - At any time, the probability of finding the system in state s at temperature T is  $P_T(s)$
- At each state s it has a potential energy  $E_s$
- The *internal energy* of the system, representing its capacity to do work, is the average:

$$U_T = \sum_{s} P_T(s) E_s$$

 The capacity to do work is counteracted by the internal disorder of the system, i.e. its entropy

$$H_T = -\sum_{S} P_T(s) \log P_T(s)$$

 The Helmholtz free energy of the system measures the useful work derivable from it and combines the two terms

$$F_T = U_T + kTH_T$$

$$= \sum_{s} P_T(s) E_s - kT \sum_{s} P_T(s) \log P_T(s)$$

$$F_T = \sum_{S} P_T(s) E_S - kT \sum_{S} P_T(s) \log P_T(s)$$

- A system held at a specific temperature anneals by varying the rate at which it visits the various states, to reduce the free energy in the system, until a minimum free-energy state is achieved
- The probability distribution of the states at steady state is known as the *Boltzmann distribution*

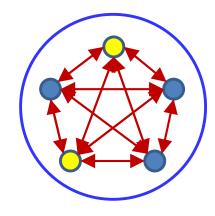

$$F_T = \sum_{s} P_T(s) E_s - kT \sum_{s} P_T(s) \log P_T(s)$$

• Minimizing this w.r.t  $P_T(s)$ , we get

$$P_T(s) = \frac{1}{Z} exp\left(\frac{-E_s}{kT}\right)$$

- Also known as the Gibbs distribution
- -Z is a normalizing constant
- Note the dependence on T
- A T = 0, the system will always remain at the lowest-energy configuration with prob = 1.

# The Energy of the Network

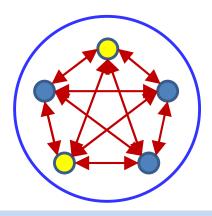

$$E(S) = -\sum_{i < j} w_{ij} s_i s_j - b_i s_i$$

$$P(S) = \frac{exp(-E(S))}{\sum_{S'} exp(-E(S'))}$$

- We can define the energy of the system as before
- Since neurons are stochastic, there is disorder or entropy (with T = 1)
- The equilibribum probability distribution over states is the Boltzmann distribution at T=1
  - This is the probability of different states that the network will wander over at equilibrium

# The Hopfield net is a distribution

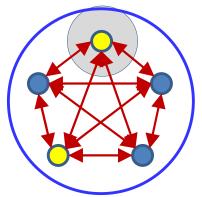

$$E(S) = -\sum_{i < j} w_{ij} s_i s_j - b_i s_i$$

$$P(S) = \frac{exp(-E(S))}{\sum_{S'} exp(-E(S'))}$$

- The stochastic Hopfield network models a probability distribution over states
  - Where a state is a binary string
  - Specifically, it models a Boltzmann distribution
  - The parameters of the model are the weights of the network
- The probability that (at equilibrium) the network will be in any state is P(S)
  - It is a *generative* model: generates states according to P(S)

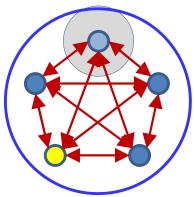

# The field at a single node

- Let S and S' be otherwise identical states that only differ in the i-th bit
  - S has i-th bit = +1 and S' has i-th bit = -1

$$P(S) = P(s_i = 1 | s_{j\neq i}) P(s_{j\neq i})$$

$$P(S') = P(s_i = -1 | s_{j\neq i}) P(s_{j\neq i})$$

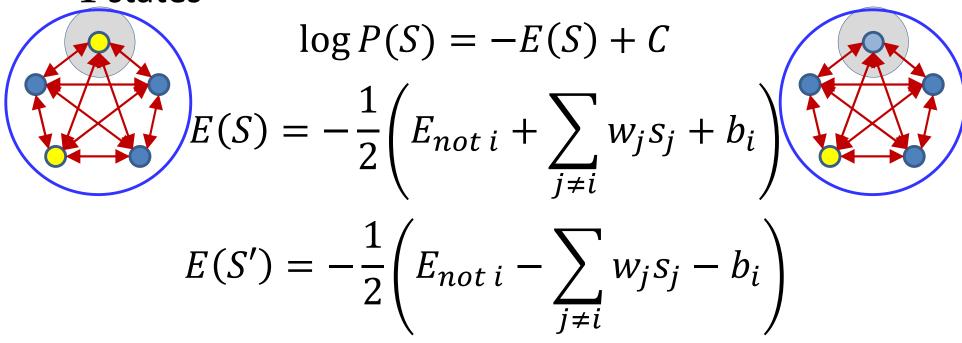

$$logP(S) - logP(S') = logP(s_i = 1|s_{j\neq i}) - logP(s_i = -1|s_{j\neq i})$$

$$logP(S) - logP(S') = log \frac{P(s_i = 1 | s_{j \neq i})}{1 - P(s_i = 1 | s_{j \neq i})}$$

# The field at a single node

Let S and S' be the states with the ith bit in the +1 and
 1 states

• 
$$logP(S) - logP(S') = E(S') - E(S) = \sum_{j \neq i} w_j s_j + b_i$$

# The field at a single node

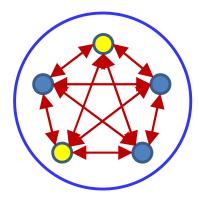

$$log\left(\frac{P(s_i = 1|s_{j\neq i})}{1 - P(s_i = 1|s_{j\neq i})}\right) = \sum_{j\neq i} w_j s_j + b_i$$

Giving us

$$P(s_i = 1 | s_{j \neq i}) = \frac{1}{1 + e^{-(\sum_{j \neq i} w_j s_j + b_i)}}$$

 The probability of any node taking value 1 given other node values is a logistic

# Redefining the network

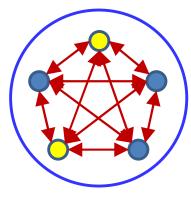

$$z_i = \sum_j w_{ji} s_j + b_i$$

$$P(s_i = 1 | s_{j \neq i}) = \frac{1}{1 + e^{-z_i}}$$

- First try: Redefine a regular Hopfield net as a stochastic system
- Each neuron is *now a stochastic unit* with a binary state  $s_i$ , which can take value 0 or 1 with a probability that depends on the local field
  - Note the slight change from Hopfield nets
  - Not actually necessary; only a matter of convenience

# The Hopfield net is a distribution

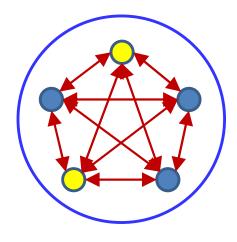

$$z_i = \sum_j w_{ji} s_j + b_i$$

$$P(s_i = 1 | s_{j \neq i}) = \frac{1}{1 + e^{-z_i}}$$

- The Hopfield net is a probability distribution over binary sequences
  - The Boltzmann distribution
- The conditional distribution of individual bits in the sequence is a logistic

# Running the network

$$z_i = \sum_j w_{ji} s_j + b_i$$

$$P(s_i = 1 | s_{j \neq i}) = \frac{1}{1 + e^{-z_i}}$$

- Initialize the neurons
- Cycle through the neurons and randomly set the neuron to 1 or -1 according to the probability given above
  - Gibbs sampling: Fix N-1 variables and sample the remaining variable
  - As opposed to energy-based update (mean field approximation): run the test  $z_i > 0$ ?
- After many many iterations (until "convergence"), sample the individual neurons
